FRENCH POLYNESIA YELLOWFIN AND BIGEYE TUNAS FISHERY

by

Arsène STEIN

Etablissement pour la Valorisation des Activités Aquacoles et Maritimes EVAAM - BP 20 Papeete TAHITI - FRENCH POLYNESIA

Working paper for the 7th Meeting of the Western Pacific Yellowfin Tuna Research Group, Nadi, Fiji, June 18 - 20, 1997.

FRENCH POLYNESIA YELLOWFIN AND BIGEYE TUNAS FISHERY

by

Arsène STEIN EVAAM BP 20 Papeete TAHITI - FRENCH POLYNESIA

1 - Presentation - fleet review

Yellowfin tuna is actually exploited by a great variety of fishing techniques : pole and line, trolling, handline and longline. On the other hand, bigeye tuna is caught only by handline and above all longline.

1. Pole and line

In 1996, the fleet comprised 92 units « bonitiers » mainly based in the Society archipelago where 85% of the population live. These vessels essentially catch skipjack and yellowfin tunas but they also catch billfishes, mahimahi and wahoo when trolling ; very few practise handline under FADs.

Summer is the best season for both skipjack and yellowfin but winter usually brings bigger fishes.

2. Handline

The fleet known as « poti marara » is specialized in the drop-stone handline technique that catch deep tuna under FADs or at « tuna holes »; in 1996, the fleet comprised about 200 units. Depending of the year, more albacore (usually) or yellowfin tuna are caught. Bigeye tuna are also caught but in a much less quantity.

Yellowfin sizes usually comprises between 18 and 30 kg whilst bigeye sizes are higher (30 to 50 kg).

These « poti marara » are polyvalent fishing units as they also practise trolling (tuna, billfishes, mahimahi, wahoo), harpoon mahimahi or scoop flying fishes (« marara ») at night.

3. Trolling

In French Polynesia, almost every existing boat use trolling at a certain time but with a wide variation of importance.

As we pointed out upper, « bonitiers » and « poti marara » commonly use trolling apart from their respective fishing speciality, but the big majority concerns the little fishing boats or game fishing boats which are about a thousand in number.

Catches, in decreasing order, consist of skipjack, yellowfin tuna, billfishes, mahimahi, wahoo, dogtooth tuna, various carangids and barracudas.

4. Longline

The domestic monofilament longliner fleet started with 2 vessels in 1990 and is planned to reach 65 active units by the end of 1997.

Vessels sizes vary from 12 m to 35 m long and gross tonnage from 9 to 150 tons.

Each operation sets between 300 and 2500 hooks, baited with imported fish, usually herring and pilchard but also horse mackerel, sanma or squid.

Longline has introduced significant changes in French Polynesia landings both in catches composition that in quality and quantity.

Indeed, « new » fishes like bigeye tuna, swordfish, striped marlin or opah for the main species, rather rare before, are now available to consumers.

Moreover, the specific processing of the catches on board has brought a new high standard of quality, that actually forces fishermen to increase the quality of their catches whatever technique they use, for the profit of consumers.

A foreign longline fleet is still authorized to fish in our EEZ. These vessels are all equipped with transponders to monitor their presence and fishing effort.

These vessels which operate in the area of the Marquesas archipelago, so between 5-12°S and 135-145°W, target bigeye tuna but catch also a great amount of yellowfin tuna.

- 1 -

2 - Longliners results

Data presented in table 1 for the recent period 1990-1996 have been compiled with regard to fishing gear and the 4 main tuna species.

We can see that although artisanal fisheries still remain preponderant for skipjack and even yellowfin tunas, longline is by far the main provider for albacore and bigeye tunas, and its importance for yellowfin tuna will increase in the future.

Table 2 summarizes the domestic longline fleet catches for the period 1994-1996.

Albacore is by far the main tuna caught, followed by yellowfin, bigeye and skipjack tunas.

A few bluefin tuna are also caught each year for a global tonnage reaching around 1 ton at all.

Graphs 1&2 show size-frequency data for yellowfin and bigeye tunas caught by domestic longliners for years 1995 and 1996; more and more effort is made to increase collection of biometric data.

An attempt to separate catches in relation to the 150°W meridian limit is presented in table 3. It shows that the east part of this limit is mainly exploited by longliners and that significant differences in yellowfin and bigeye tunas CPUE exist.

It is important also to point out that foreign longliners in the recent years have exclusively exploited the area east of 150°W, targeting bigeye tuna.

Maps 1 to 4 show a representation of domestic longliners deployment during the period 1994-1996, with the mean CPUE obtained; data used for these graphs cover 48% of the total amount of fishing effort data for the period. CPUE values plotted are considered good estimations but the real fishing effort map would show a much greater importance of the 1000 km diameter circle area centered on Tahiti island, the main home longliner port.

No fundamental changes have been recorded in the longline material gear nor in the setting of the line; the few general variations would concern :

- a constant increase, each year, in the number of hooks set per fishing operation that underlies a better utilization rate of the vessels;
- a strong variation in the bait used : almost exclusively herring in 1994 and 1995; a mixture of herring and pilchard (sardine) in 1996 and the large dominance of pilchard for the first half of 1997; both better prices and apparently better yields explain the extension of pilchard actually.

Live-bait have not been used by longliners until now, although rough results known from Taiwanese experiments in Guam area are about to re-activate an ancient live-bait production program for milkfish.

The foreign longliners catches composition is very different from the domestic one as bigeye tuna is preponderant. Many things can explain this, in particular fact that this species is specifically targeted and that these vessels operate in a network.

Maps 5&6 give data for the period 1984-1992 for Japanese, Korean and Taiwanese vessels for a total fishing effort of 26.5 million hooks, and a production of :

- 8.5 thousand tons of bigeye,
- •3.4 thousand tons of yellowfin,
- 0.9 thousand tons of albacore and
- 1 ton of skipjack.

It appears clear that skipjack and bluefin tunas are under-reported.

3 - Miscellaneous

- 4 vessels have experienced typical swordfish longlining in 1996 and 1997; results seem to show that the resource well exists but is generally rather far away from Tahiti and is subject to seasonal influences.
- a tagged bigeye tuna has been recovered on April 8th 1997. It was caught by a longliner by 153°30'W / 16°10'S and measured 132 cm (FL) for 46 kg (gilled & gutted weight). Information provided by SPC indicates that this fish had been tagged on October 26th 1991 by 147°03'E / 15°22'S near Australia; at that time, it was 80 cm long. This fish has been living 1991 days (5 years and 5 months) at sea after tagging and cruised a minimum 3420 Nm. If we base one's argument on this fish, bigeye tuna growth seems to be rather slow compared to a few existing growth models.
- Since 1992 and till now, 12 yellowfin and 4 bigeye tunas have been monitored in their movement by acoustic tags in relation to a research program developed in French Polynesia on tuna behaviour. Final results are expected by 1998.
